Abstract	<p>Purpose of the study: To identify the concerns of chronically ill elderly people living alone or cohabiting with others in the coronary disasters. Methods: A questionnaire survey using Internet research was administered to elderly people living alone and cohabiting with others who have chronic diseases. The questions included basic attributes of the participants (age, gender, unmarried/married, name of disease, etc.) and concerns about the Corona Disaster (free description). The data obtained were qualitatively summarized and categorized. Results: Responses were obtained from a total of 208 people: 104 elderly people living alone and 104 elderly people living together with a chronic disease. The mean age was 71.3 years (SD ± 5.3), 154 (74%) were male and 54 (26%) were female. Concerns in the coronary disaster were classified into five categories: "COVID-19 related," "social changes," "psychological changes," "physical changes," and "daily life. The most important concern for both single residents and those living together was the risk of infection due to pre-existing medical conditions. Elderly persons living together were particularly concerned about infecting family members. Elderly persons living alone may face difficulties in daily life, such as receiving medical examinations and medicines, as well as financial and psychological concerns.</p>
