Abstract	<p>When a wheelchair is used, seating can maximize the subject's abilities, including improvement of ADLs, by improving the two elements of "moving" and "sitting". This paper outlines the purpose of seating, the current status of wheelchairs in Japan, evaluation of wheelchair seating, and approaches to sling seat deflection, and presents a case of a woman in her 80s who was being considered for diaper use due to incontinence. The most important aspects of the seating intervention in this case were (1) anterior sciatic support, (2) thigh support, and (3) sacral support in the sitting posture, which were adjusted by wheelchair cushion and back tension. The patient's failure due to urge incontinence improved as a result of the improved wheelchair drive, and the patient became independent in toileting. Thus, we described the possibility of seating that enables the patient to continue to use the toilet as desired even without a wheelchair change.</p>
