Abstract	<p>The purpose of this study was to analyze occupational therapy practice in case reports of eating and swallowing disorders in the elderly, to discuss the future of occupational therapy, and to help establish occupational therapy expertise in this field. A literature search yielded 25 cases for analysis, and an abstract table was created. Interventions were ordered by frequency of occurrence and classified by ICF. As a result, 17 interventions were categorized into physical and mental functions and structures, 8 interventions into activities and participation, and 5 interventions into environmental factors. On the other hand, there was no clear occupational therapy practice for individual factors. Therefore, the future occupational therapy in the field of eating and swallowing should not focus too much on psychosomatic functions and structures, but should give sufficient consideration to individual factors.</p> <p>Translated with www.DeepL.com/Translator (free version)</p>
