| Abstract | <p>The presented case was taking care of his wife with dementia while he was suffering from a number of physical illnesses, and the burden of caregiving was heavy. However, it was thought that his participation in the family association reduced the psychological burden of caregiving, and furthermore, taking care of others as a caretaker of the family association led to a reduction in the social burden of caregiving. The fact that the patients were relatively financially well-off was thought to have contributed to their acquisition of the role of caretaker. In our quantitative study on the sense of financial burden among male caregivers of dementia patients, we found that the caregiving burden and the sense of emotional exhaustion tended to increase as the perceived level of financial comfort decreased. These results suggest that health care providers should consider the economic status of family members when planning care for patients with dementia in order to create an environment that leads to better care.</p> |
