Abstract	<p>The validities of setting the upper and lower limits of psychological vital sign (PVS) were studied at 8 nursing schools. Of the PVS which we defined the stress self-regulation inventory(SSI) was composed of “social support”, “sufficiency achievement motivation”, “personal affinity”, “competitive achievement motivation”, “competent sense of movement” !affinity with heterosexuality”, “physical Vulnerability”, “psychological vulnerability” “problem focus coping”, “emotional focus treatment”, “self-esteem”, and “existential sense”, items. Profile of mood states(POMS)was composed of “tension-anxiety”, “depression-dejection”, “anger-hostility”, “vigor”, “fatigue”, and “confusion” items. Monitor-Blunter Style Scale (MBSS) evaluated the individual psychological response style. The stress degree was represented by the feeling of stress at present when the stress on admission was set to 50.</p> <p>Five hundred forty-four and 478 students just before and after practicing the clinical training were enrolled in this study, respectively. The graphical representations of upper and lower limit values of PVS in the 8 schools tended to be similar ; however, there were some scales which showed statistical difference between the 8 schools by one-way ANOVA. Considering their diversities, the upper And lower limit values of PVS should be established by each school.</p> <p>Our next task is to develop a self-assessment systems of PVS that enables nursing students to grasp the diversified and over time resources, such as mood states, individual psychological response style and resilience.</p>
keyword	Psychological vital sign, upper and lower limits, resilience, stress, nursing students
