Abstract	<p>This study focused on coping and burnout related to provision of care among male caregivers of people with dementia living at home. It is estimated that 25% of those aged over 65 years will have dementia by 2025. Extra care is required for people with dementia who have behavioral and psychological symptoms. This increased caregiving demand places stress on caregivers and may affect their psychological health. Increasing numbers of unmarried or divorced persons have resulted in changes in family structure and an increase in family size. Therefore the number of male caregivers has also increased. The perpetrators is 70%、murder/abuse cause of homecare are male caregivers. Difficulties experienced by male caregivers include the care burden、 coping with care problems、 and burnout. This study found a Male caregivers with dementia living at home of burn out has influence symptoms and independently performing daily activities of dementia. Our finding suggest that we needs to be support for each male caregiver`s coping style.</p>
